- Hadoop
 - Basic Concepts
 - MapReduce
 - YARN
- Objectives
 - 能够针对大数据批处理需求，设计并实现基于MapReduce/YARN的并行处理方案

- The Apache™ Hadoop® project
 - develops open-source software for reliable, scalable, distributed computing.
- The Apache Hadoop software library
 - is a framework that allows for the distributed processing of large data sets across clusters of computers using simple programming models.
 - It is designed to scale up from single servers to thousands of machines, each offering local computation and storage.
 - Rather than rely on hardware to deliver high-availability, the library itself is designed to detect and handle failures at the application layer, so delivering a highly-available service on top of a cluster of computers, each of which may be prone to failures.
- <https://hadoop.apache.org>

- The project includes these modules:
 - **Hadoop Common:** The common utilities that support the other Hadoop modules.
 - **Hadoop Distributed File System (HDFS™):** A distributed file system that provides high-throughput access to application data.
 - **Hadoop YARN:** A framework for job scheduling and cluster resource management.
 - **Hadoop MapReduce:** A YARN-based system for parallel processing of large data sets.
 - **Hadoop Ozone:** An object store for Hadoop.

Pseudo-Distributed Operation

- etc/hadoop/core-site.xml:

```
<configuration>
  <property>
    <name>fs.defaultFS</name>
    <value>hdfs://localhost:9000</value>
  </property>
  <property>
    <name>hadoop.tmp.dir</name>
    <value>/var/hadoop</value>
  </property>
</configuration>
```
- etc/hadoop/hdfs-site.xml:

```
<configuration>
  <property>
    <name>dfs.replication</name>
    <value>1</value>
  </property>
</configuration>
```

Setup passphraseless ssh

- Now check that you can ssh to the localhost without a passphrase:
- `$ ssh localhost`
- If you cannot ssh to localhost without a passphrase, execute the following commands:
 - `$ ssh-keygen -t rsa -P "" -f ~/.ssh/id_rsa`
 - `$ cat ~/.ssh/id_rsa.pub >> ~/.ssh/authorized_keys`
 - `$ chmod 0600 ~/.ssh/authorized_keys`
- Setup dfs directories
 - `$ sudo mkdir /var/hadoop`
 - `$ sudo mkdir /var/hadoop/dfs`
 - `$ sudo mkdir /var/hadoop/dfs/name`
 - `$ sudo chmod -R a+w /var/hadoop`

- Format the filesystem:
`$ bin/hdfs namenode -format`
- Start NameNode daemon and DataNode daemon:
`$ sbin/start-dfs.sh`
- Browse the web interface for the NameNode; by default it is available at:
 - NameNode - <http://localhost:9870/>

Hadoop	Overview	Datanodes	Datanode Volume Failures	Snapshot	Startup Progress	Utilities ▾
--------	----------	-----------	--------------------------	----------	------------------	-------------

Overview 'localhost:9000' (active)

Started:	Sat Dec 04 14:00:39 +0800 2021
Version:	3.2.2, r7a3bc90b05f257c8ace2f76d74264906f0f7a932
Compiled:	Sun Jan 03 17:26:00 +0800 2021 by hexiaoqiao from branch-3.2.2
Cluster ID:	CID-3046ebbb-8b04-485e-aa0f-9061e6d6087f
Block Pool ID:	BP-1664417573-127.0.0.1-1638597623149

Summary

Security is off.

Safemode is off.

1 files and directories, 0 blocks (0 replicated blocks, 0 erasure coded block groups) = 1 total filesystem object(s).

Heap Memory used 105.33 MB of 161 MB Heap Memory. Max Heap Memory is 4 GB.

Non Heap Memory used 47.82 MB of 52 MB Committed Non Heap Memory. Max Non Heap Memory is <unbounded>.

Configured Capacity:	931.55 GB
Configured Remote Capacity:	0 B
DFS Used:	4 KB (0%)

Map Reduce

- OSDI'04
 - MapReduce: Simplified Data Processing on Large Clusters

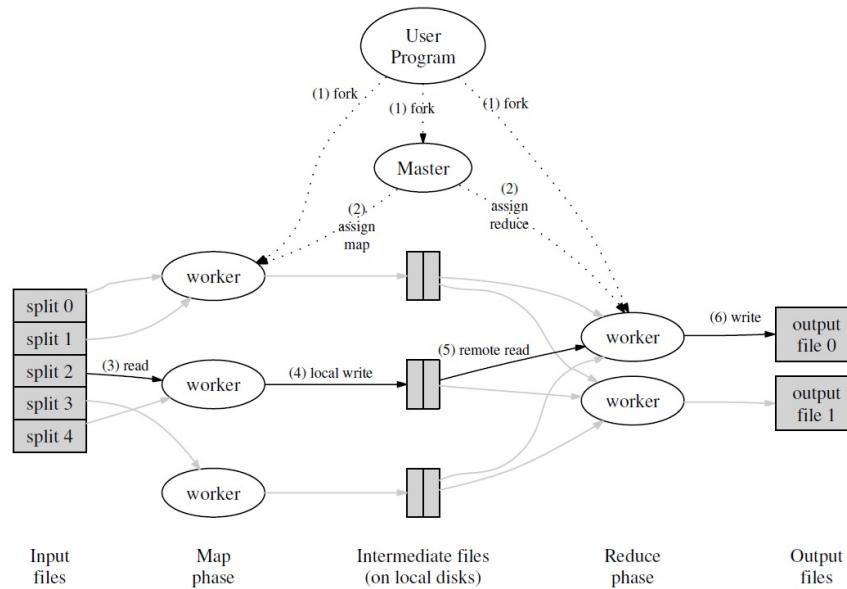

Figure 1: Execution overview

- Pseudo-code
 - Word Count Example

```
map(String key, String value):  
    // key: document name  
    // value: document contents  
    for each word w in value:  
        EmitIntermediate(w, "1");  
  
reduce(String key, Iterator values):  
    // key: a word  
    // values: a list of counts  
    int result = 0;  
    for each v in values:  
        result += ParseInt(v);  
    Emit(AsString(result));
```

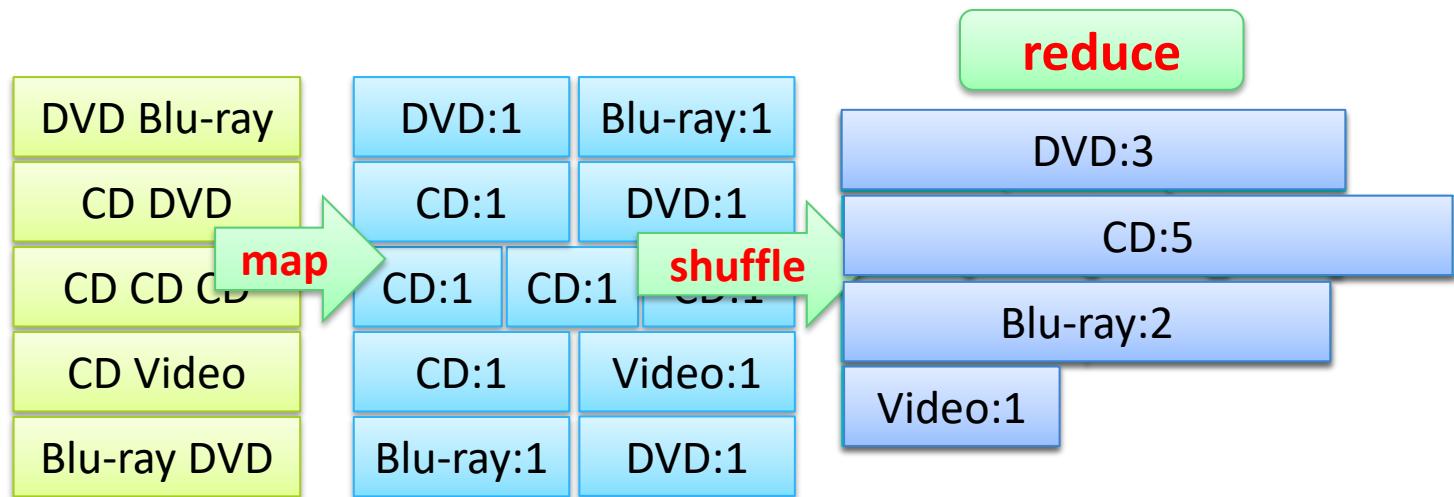

- The MapReduce framework
 - operates exclusively on $\langle \text{key}, \text{value} \rangle$ pairs, that is, the framework views the input to the job as a set of $\langle \text{key}, \text{value} \rangle$ pairs and produces a set of $\langle \text{key}, \text{value} \rangle$ pairs as the output of the job, conceivably of different types.
- The key and value classes
 - have to be serializable by the framework and hence need to implement the [Writable](#) interface. Additionally, the key classes have to implement the [WritableComparable](#) interface to facilitate sorting by the framework.
- Input and Output types of a MapReduce job:
 - (input) $\langle \text{k1}, \text{v1} \rangle \rightarrow \text{map} \rightarrow \langle \text{k2}, \text{v2} \rangle \rightarrow \text{combine} \rightarrow \langle \text{k2}, \text{v2} \rangle \rightarrow \text{reduce} \rightarrow \langle \text{k3}, \text{v3} \rangle$ (output)

MapReduce Basics

- Paradigm

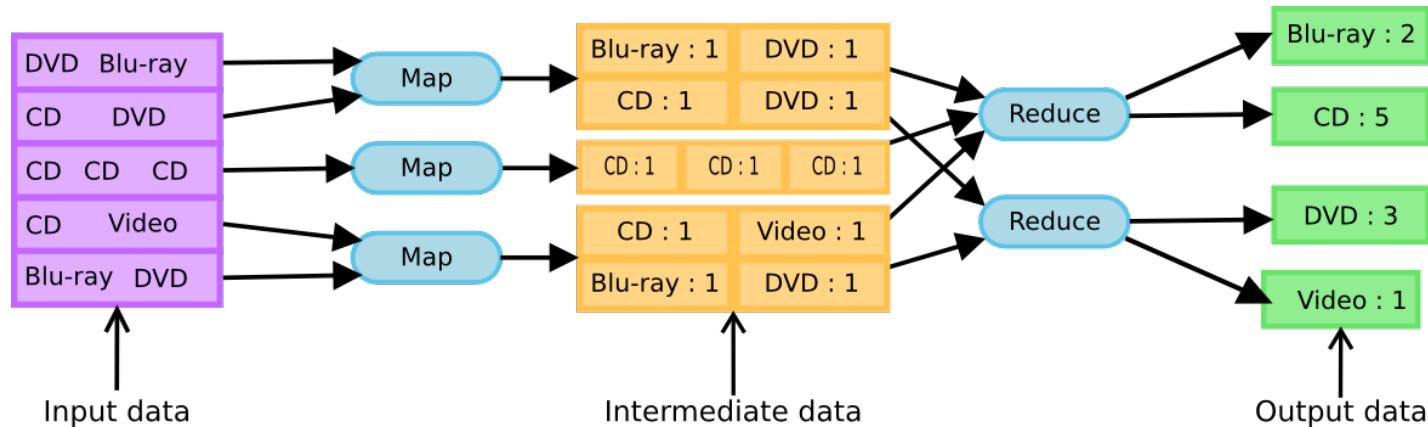

- *map* $(k1, v1)$ $\rightarrow list(k2, v2)$
- *reduce* $(k2, list(v2))$ $\rightarrow list(k3, v3)$

- Word Count

MapReduce Basics

- Execution View

Map Reduce - WordCount

```
public class WordCount {  
  
    public static class TokenizerMapper  
        extends Mapper<Object, Text, Text, IntWritable>{  
  
        private final static IntWritable one = new IntWritable(1);  
        private Text word = new Text();  
  
        public void map(Object key, Text value, Context context  
        ) throws IOException, InterruptedException {  
            StringTokenizer itr = new StringTokenizer(value.toString());  
            while (itr.hasMoreTokens()) {  
                word.set(itr.nextToken());  
                context.write(word, one);  
            }  
        }  
    }  
}
```

Map Reduce - WordCount

```
public static class IntSumReducer
    extends Reducer<Text,IntWritable,Text,IntWritable> {
    private IntWritable result = new IntWritable();

    public void reduce(Text key, Iterable<IntWritable> values,
                      Context context
    ) throws IOException, InterruptedException {
        int sum = 0;
        for (IntWritable val : values) {
            sum += val.get();
        }
        result.set(sum);
        context.write(key, result);
    }
}
```

Map Reduce - WordCount

```
public static void main(String[] args) throws Exception {  
    Configuration conf = new Configuration();  
    conf.set("dfs.defaultFS", "hdfs://hadoop:9000");  
    Job job = Job.getInstance(conf, "word count");  
    job.setJarByClass(WordCount.class);  
    job.setMapperClass(TokenizerMapper.class);  
    job.setCombinerClass(IntSumReducer.class);  
    job.setReducerClass(IntSumReducer.class);  
    job.setOutputKeyClass(Text.class);  
    job.setOutputValueClass(IntWritable.class);  
    FileInputFormat.addInputPath(job, new Path(args[0]));  
    FileOutputFormat.setOutputPath(job, new Path(args[1]));  
    System.exit(job.waitForCompletion(true) ? 0 : 1);  
}
```

Map Reduce - WordCount

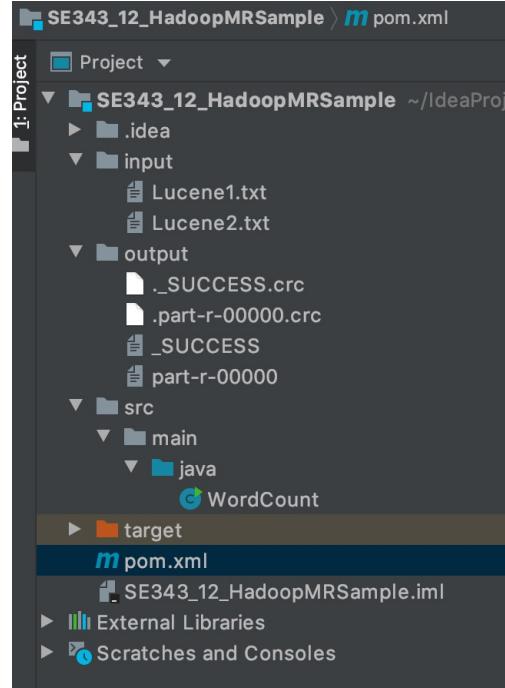

```
<dependencies>
    <dependency>
        <groupId>org.apache.hadoop</groupId>
        <artifactId>hadoop-common</artifactId>
        <version>3.2.1</version>
    </dependency>
    <dependency>
        <groupId>org.apache.hadoop</groupId>
        <artifactId>hadoop-mapreduce-client-core</artifactId>
        <version>3.2.1</version>
    </dependency>
    <dependency>
        <groupId>org.apache.hadoop</groupId>
        <artifactId>hadoop-mapreduce-client-common</artifactId>
        <version>3.2.1</version>
    </dependency>
</dependencies>
</project>
```

Map Reduce - WordCount

- file01
Hello World Bye World
- file01
Hello Hadoop Bye Hadoop

- part-r-0000001
Bye 1
Goodbye 1
Hadoop 2
Hello 2
World 2

Map Reduce - WordCount

```
public void map(Object key, Text value, Context context
) throws IOException, InterruptedException {
    StringTokenizer itr = new StringTokenizer(value.toString());
    while (itr.hasMoreTokens()) {
        word.set(itr.nextToken());
        context.write(word, one);
    }
}
```

- For the given sample input the first map emits:

```
< Hello, 1>
< World, 1>
< Bye, 1>
< World, 1>
```

- The second map emits:

```
< Hello, 1>
< Hadoop, 1>
< Goodbye, 1>
< Hadoop, 1>
```

Map Reduce - WordCount

```
job.setCombinerClass(IntSumReducer.class);
```

- The output of the first map:

< Bye, 1>

< Hello, 1>

< World, 2>

- The output of the second map:

< Goodbye, 1>

< Hadoop, 2>

< Hello, 1>

Map Reduce - WordCount

```
public void reduce(Text key, Iterable<IntWritable> values,
                  Context context
) throws IOException, InterruptedException {
    int sum = 0;
    for (IntWritable val : values) {
        sum += val.get();
    }
    result.set(sum);
    context.write(key, result);
}
```

- Thus the output of the job is:

```
< Bye, 1>
< Goodbye, 1>
< Hadoop, 2>
< Hello, 2>
< World, 2>
```

- A Weather Dataset

- The data we will use is from the National Climatic Data Center (NCDC, <http://www.ncdc.noaa.gov/>). The data is stored using a line-oriented ASCII format, in which each line is a record.
- Sample: The line has been split into multiple lines to show each field: in the real file, fields are packed into one line with no delimiters.

```
0057
332130 # USAF weather station identifier
99999 # WBAN weather station identifier
19500101 # observation date
0300     # observation time
4
+51317   # latitude (degrees x 1000)
+028783  # longitude (degrees x 1000)
FM-12
+0171    # elevation (meters)
.....
```

- MapReduce works by breaking the processing into two phases: the map phase and the reduce phase.
 - Each phase has key-value pairs as input and output, the types of which may be chosen by the programmer.
 - The programmer also specifies two functions: the map function and the reduce function.

- The input to our **map** phase is the raw NCDC data.
 - We choose a text input format that gives us each line in the dataset as a text value.
 - The key is the offset of the beginning of the line from the beginning of the file.
- This map function is simple.
 - We pull out the year and the air temperature, since these are the only fields we are interested in.
 - In this case, the map function is just a data preparation phase, setting up the data in such a way that the reducer function can do its work on it: finding the maximum temperature for each year.
 - The map function is also a good place to drop bad records: here we filter out temperatures that are missing, suspect, or erroneous.

- To visualize the way the map works, consider the following sample lines of input data

006701199099991950051507004...9999999N9+00001+99999999999...

004301199099991950051512004...9999999N9+00221+99999999999...

004301199099991950051518004...9999999N9-00111+99999999999...

004301265099991949032412004...0500001N9+01111+99999999999...

004301265099991949032418004...0500001N9+00781+99999999999...

- These lines are presented to the map function as the key-value pairs:

(0, 006701199099991950051507004...9999999N9+00001+99999999999...)

(106, 004301199099991950051512004...9999999N9+00221+99999999999...)

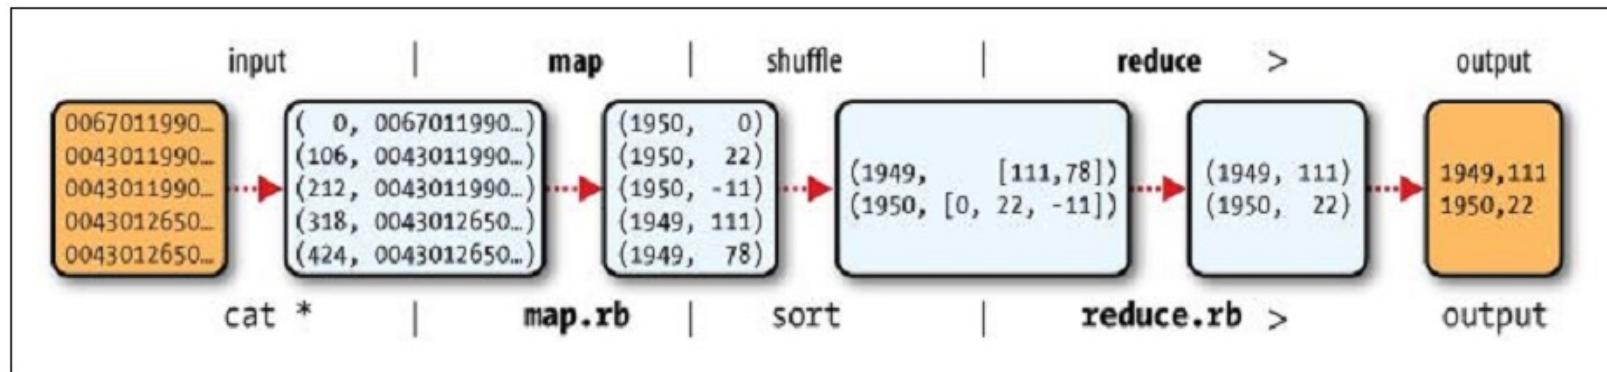

(212, 004301199099991950051518004...9999999N9-00111+99999999999...)

(318, 004301265099991949032412004...0500001N9+01111+99999999999...)

(424, 004301265099991949032418004...0500001N9+00781+99999999999...)

- The keys are the line offsets within the file, which we ignore in our map function.
 - The map function merely extracts the year and the air temperature (indicated in bold text), and emits them as its output (the temperature values have been interpreted as integers):
 $(1950, 0)$
 $(1950, 22)$
 $(1950, -11)$
 $(1949, 111)$
 $(1949, 78)$
- The output from the map function is processed by the MapReduce framework before being sent to the reduce function.
- This processing sorts and groups the key-value pairs by key.
 - So, continuing the example, our reduce function sees the following input:
 $(1949, [111, 78])$
 $(1950, [0, 22, -11])$
- Each year appears with a list of all its air temperature readings.

- All the reduce function has to do now is iterate through the list and pick up the maximum reading:
`(1949, 111)`
`(1950, 22)`
- This is the final output:
 - the maximum global temperature recorded in each year.

```
public class MaxTemperatureMapper
    extends Mapper<LongWritable, Text, Text, IntWritable> {
    private static final int MISSING = 9999;
    @Override
    public void map(LongWritable key, Text value, Context context)
        throws IOException, InterruptedException {
        String line = value.toString();
        String year = line.substring(15, 19);
        int airTemperature;
        if (line.charAt(87) == '+') { // parseInt doesn't like leading plus signs
            airTemperature = Integer.parseInt(line.substring(88, 92));
        } else {
            airTemperature = Integer.parseInt(line.substring(87, 92));
        }
        String quality = line.substring(92, 93);
        if (airTemperature != MISSING && quality.matches("[01459]")) {
            context.write(new Text(year), new IntWritable(airTemperature));
        }
    }
}
```

```
public class MaxTemperatureReducer
    extends Reducer<Text, IntWritable, Text, IntWritable> {
    @Override
    public void reduce(Text key, Iterable<IntWritable> values,
                      Context context)
        throws IOException, InterruptedException {
        int maxValue = Integer.MIN_VALUE;
        for (IntWritable value : values) {
            maxValue = Math.max(maxValue, value.get());
        }
        context.write(key, new IntWritable(maxValue));
    }
}
```

Java MapReduce

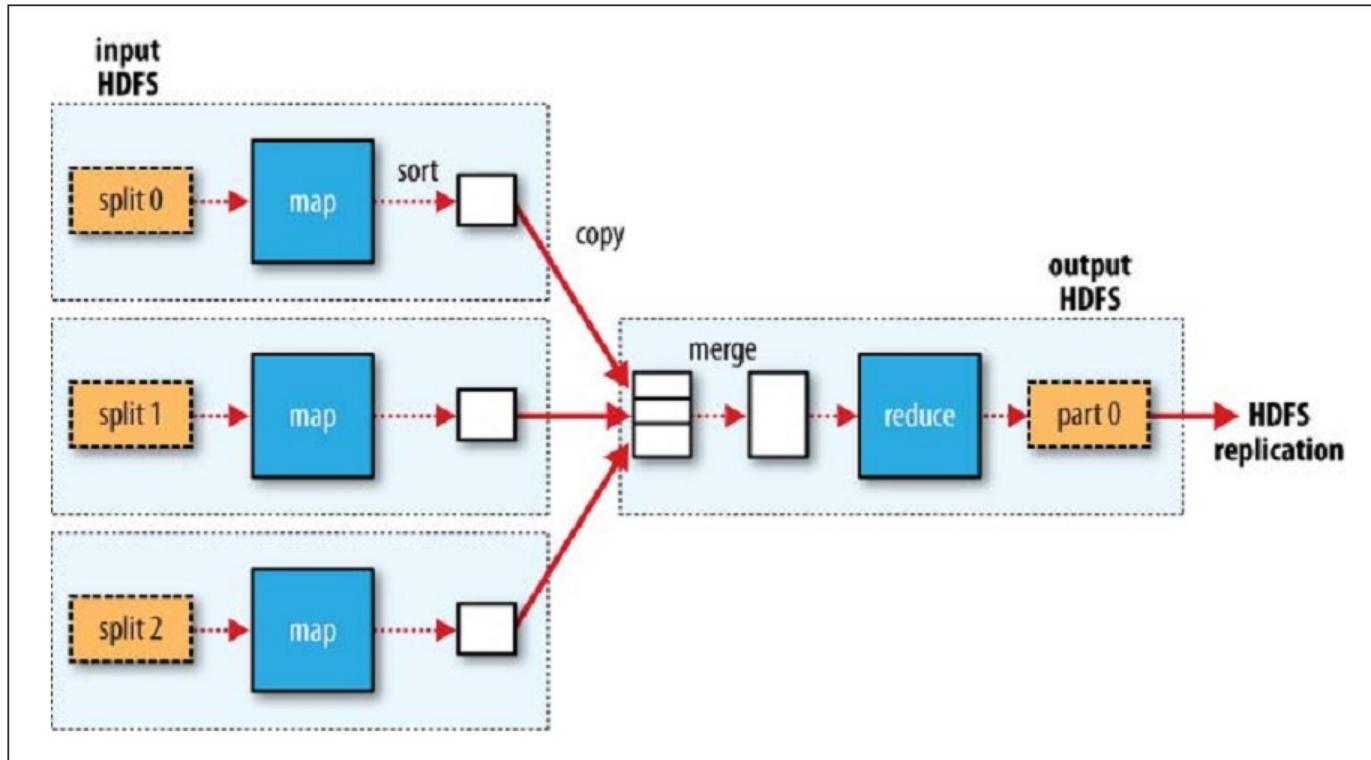

```
public class MaxTemperature {  
    public static void main(String[] args) throws Exception {  
        if (args.length != 2) {  
            System.err.println("Usage: MaxTemperature <input path> <output path>");  
            System.exit(-1);  
        }  
        Configuration conf = new Configuration();  
        conf.set("dfs.defaultFS", "hdfs://hadoop:9000");  
        Job job = Job.getInstance(conf, "max temperature");  
        job.setJarByClass(MaxTemperature.class);  
        job.setJobName("Max temperature");  
        FileInputFormat.addInputPath(job, new Path(args[0]));  
        FileOutputFormat.setOutputPath(job, new Path(args[1]));  
  
        job.setMapperClass(MaxTemperatureMapper.class);  
        job.setReducerClass(MaxTemperatureReducer.class);  
  
        job.setOutputKeyClass(Text.class);  
        job.setOutputValueClass(IntWritable.class);  
  
        System.exit(job.waitForCompletion(true) ? 0 : 1);  
    }  
}
```

output2/part-r-00000		
1	1901	317
2	1902	244

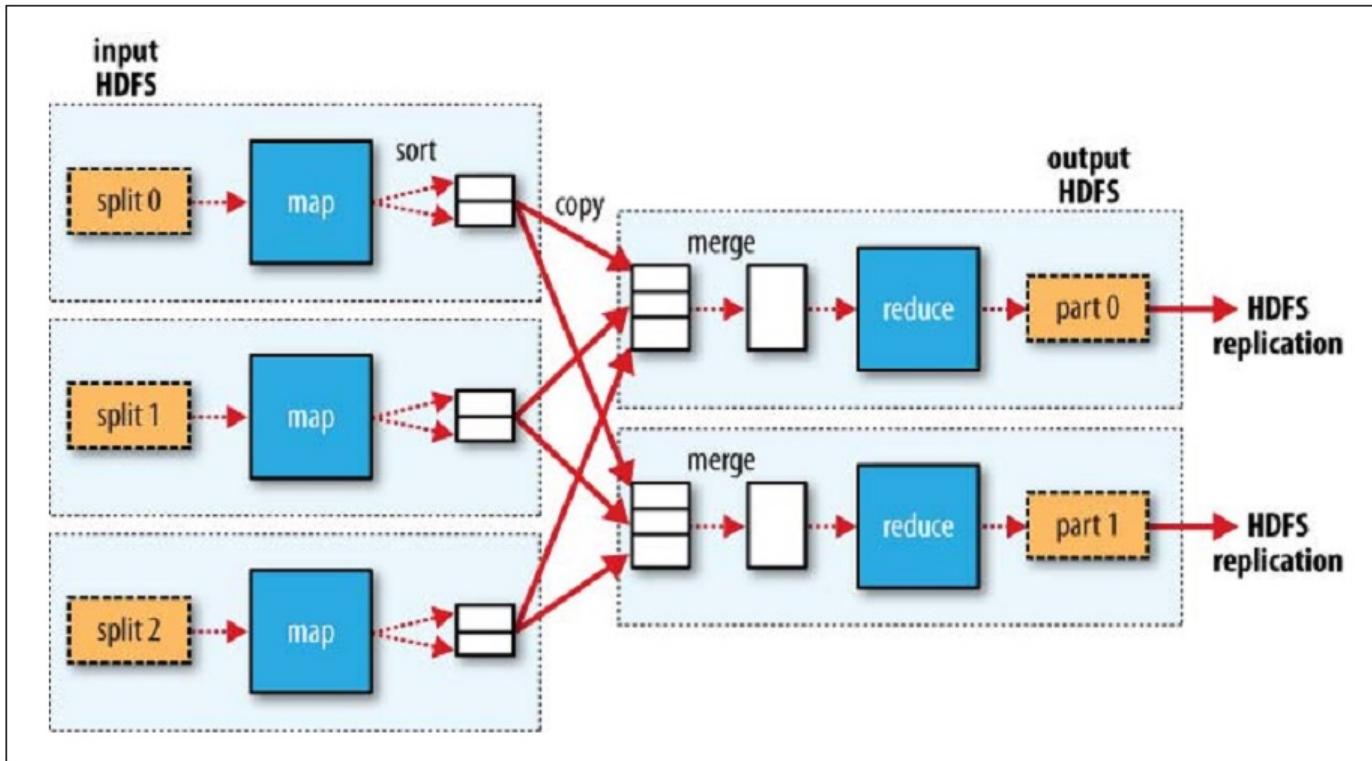

- To scale out, we need to store the data in a distributed file system, typically HDFS
 - to allow Hadoop to move the MapReduce computation to each machine hosting a part of the data.
- A MapReduce job is a unit of work that the client wants to be performed:
 - it consists of the input data, the MapReduce program, and configuration information.
 - Hadoop runs the job by dividing it into tasks, of which there are two types: map tasks and reduce tasks.

- Hadoop divides the input to a MapReduce job into fixed-size pieces called **input splits**, or just **splits**.
 - Hadoop creates one map task for each split, which runs the user defined map function for each record in the split.
- Having many splits means the time taken to process each split is small compared to the time to process the whole input.
 - On the other hand, if splits are too small, then the overhead of managing the splits and of map task creation begins to dominate the total job execution time.
 - For most jobs, a good split size tends to be the size of an HDFS block, **64 MB** by default.

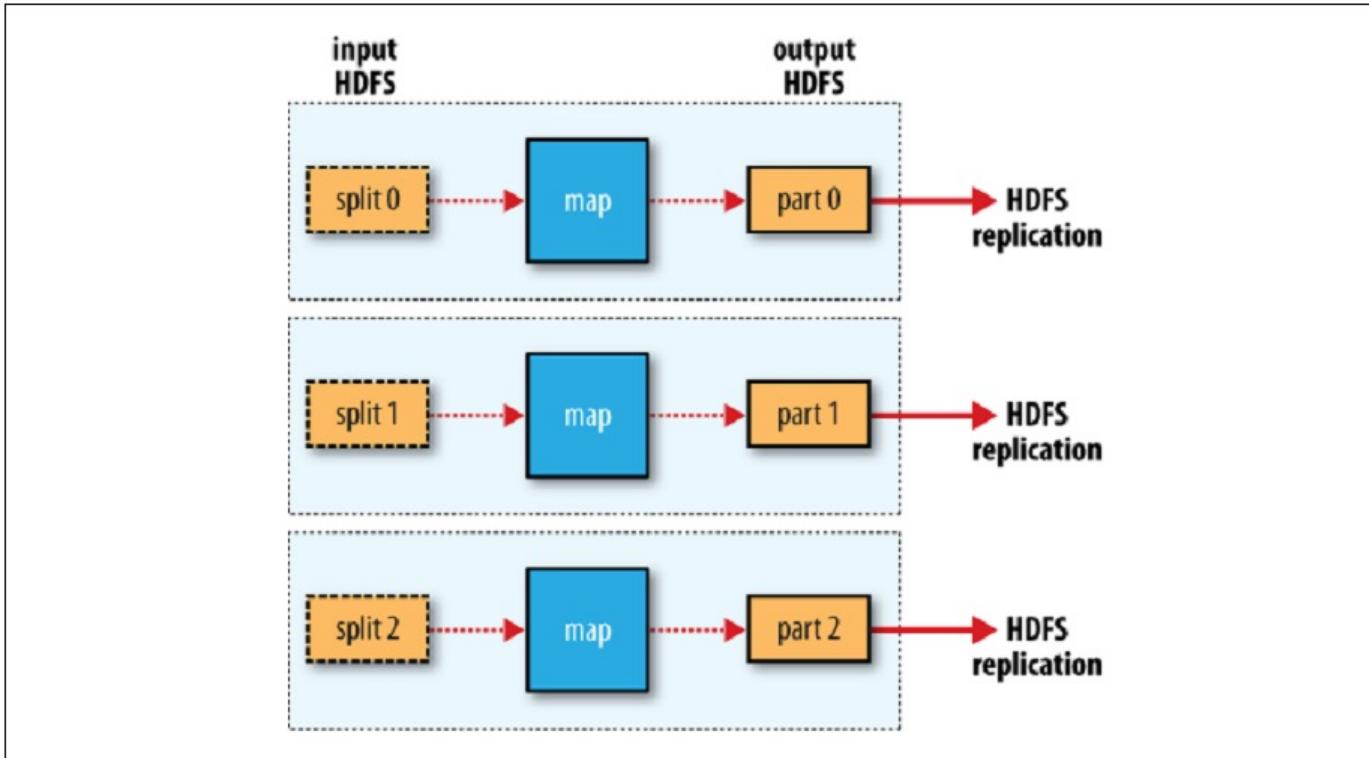

Scaling Out

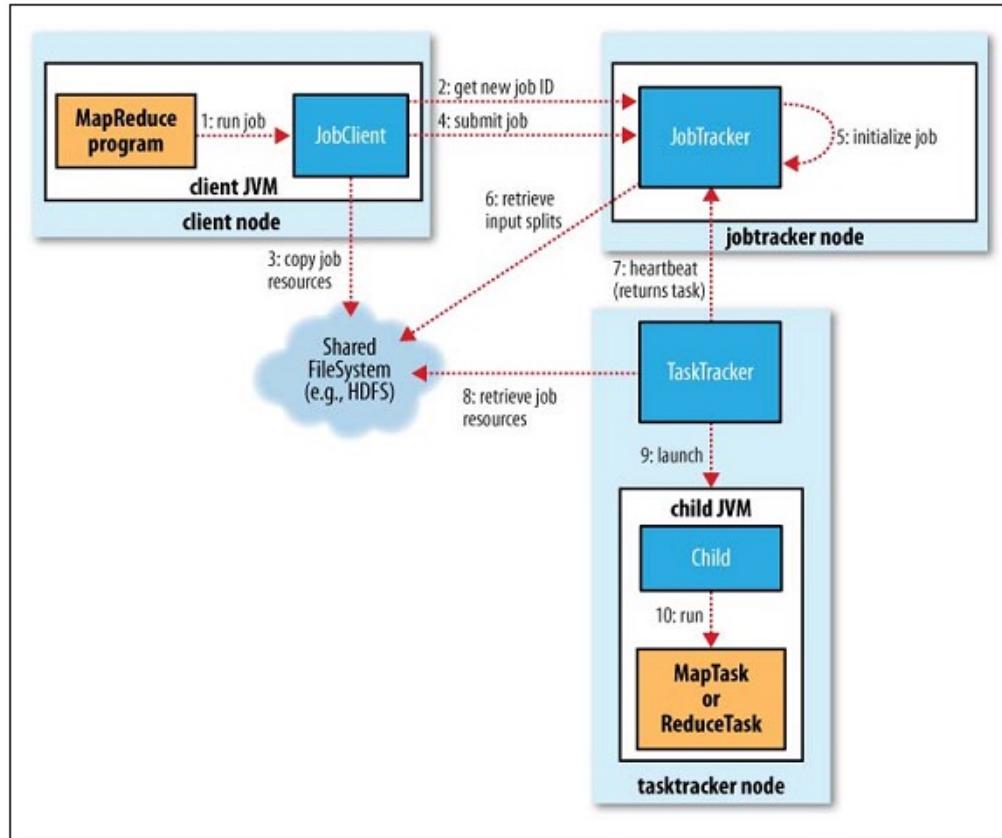

Scaling Out

Scaling Out

MapReduce inside: JobTracker

- Mapper maps input **key/value pairs** to a set of **intermediate** key/value pairs.
 - Maps are the **individual tasks** that transform input records into intermediate records.
 - The transformed intermediate records **do not** need to be of the same type as the input records.
 - A given input pair may map to zero or many output pairs.
- The Hadoop MapReduce framework spawns **one map task for each InputSplit** generated by the **InputFormat** for the job.
 - Overall, mapper implementations are passed to the job via [`Job.setMapperClass\(Class\)`](#) method.
 - The framework then calls [`map\(WritableComparable, Writable, Context\)`](#) for each key/value pair in the InputSplit for that task.
 - Applications can then override the **cleanup(Context)** method to perform any required cleanup.
- Output pairs do not need to be of the same types as input pairs.
 - A given input pair may map to zero or many output pairs.
 - Output pairs are collected with calls to [`context.write\(WritableComparable, Writable\)`](#).

- All **intermediate** values associated with a given **output key** are subsequently grouped by the framework,
 - and passed to the **Reducer(s)** to determine the final output.
 - Users can control the grouping by specifying a **Comparator** via [`Job.setGroupingComparatorClass\(Class\)`](#).
- The Mapper outputs are **sorted** and then **partitioned** per Reducer.
 - **The total number of partitions** is the same as the number of reduce tasks for the job.
 - Users can control which keys (and hence records) go to which Reducer by implementing a custom **Partitioner**.
- Users can optionally specify a **combiner**, via [`Job.setCombinerClass\(Class\)`](#),
 - to perform **local aggregation of the intermediate outputs**, which helps to cut down the amount of data transferred from the Mapper to the Reducer.
 - The intermediate, sorted outputs are always stored in a simple (key-len, key, value-len, value) format.

How Many Mappers?

- The number of maps is usually driven by the **total size of the inputs**, that is,
 - the **total number of blocks** of the input files.
- The right level of parallelism for maps seems to be around **10-100 maps per-node**,
 - although it has been set up to 300 maps for very cpu-light map tasks.
 - **Task setup takes a while**, so it is best if the maps take at least a minute to execute.
- Thus,
 - if you expect 10TB of input data and have a blocksize of 128MB, you'll end up with 82,000 maps,
 - unless **Configuration.set(MRJobConfig.NUM_MAPS, int)** (which only provides a hint to the framework) is used to set it even higher.

- Reducer reduces a set of **intermediate** values which share a key to a **smaller** set of values.
 - The number of reduces for the job is set by the user via [`Job.setNumReduceTasks\(int\)`](#).
 - Overall, Reducer implementations are passed the Job for the job via the [`Job.setReducerClass\(Class\)`](#) method and can override it to initialize themselves.
 - The framework then calls [`reduce\(WritableComparable, Iterable<Writable>, Context\)`](#) method for each **<key, (list of values)>** pair in the grouped inputs.
 - Applications can then override the [`cleanup\(Context\)`](#) method to perform any required cleanup.
- Reducer has 3 primary phases: **shuffle**, **sort** and **reduce**.

- **Shuffle**

- Input to the Reducer is the sorted output of the mappers.
- In this phase the framework fetches the **relevant partition** of the output of all the mappers, via **HTTP**.

- **Sort**

- The framework groups Reducer inputs by **keys** (since different mappers may have output the same key) in this stage.
- The shuffle and sort phases occur **simultaneously**; while map-outputs are being fetched they are merged.

- **Secondary Sort**

- If equivalence rules for grouping the intermediate keys are required to be different from those for grouping keys before reduction,
- then one may specify a **Comparator** via [`Job.setSortComparatorClass\(Class\)`](#).
- Since [`Job.setGroupingComparatorClass\(Class\)`](#) can be used to control how intermediate keys are grouped, these can be used in conjunction to simulate *secondary sort on values*.

- **Reduce**

- In this phase the [`reduce\(WritableComparable, Iterable<Writable>, Context\)`](#) method is called for each `<key, (list of values)>` pair in the grouped inputs.
- The output of the reduce task is typically written to the [`FileSystem`](#) via [`Context.write\(WritableComparable, Writable\)`](#).
- The output of the Reducer is *not sorted*.

How Many Reducers?

- The right number of reduces seems to
 - be 0.95 or 1.75 multiplied by (*<no. of nodes> * <no. of maximum containers per node>*).
 - With 0.95 all of the reduces can launch immediately and start transferring map outputs as the maps finish.
 - With 1.75 the faster nodes will finish their first round of reduces and launch a second wave of reduces doing a much better job of load balancing.
- Increasing the number of reduces
 - increases the framework overhead,
 - but increases load balancing and lowers the cost of failures.
- The scaling factors above are slightly less than
 - whole numbers to reserve a few reduce slots in the framework for speculative-tasks and failed tasks.

- **Reducer NONE**

- It is legal to set the number of reduce-tasks to **zero** if no reduction is desired.
- In this case the outputs of the map-tasks go directly to the FileSystem, into the output path set by [`FileOutputFormat.setOutputPath\(Job, Path\)`](#).
- The framework **does not sort** the map-outputs before writing them out to the FileSystem.

- **Partitioner**

- [Partitioner](#) partitions the key space.
- Partitioner controls the partitioning of the keys of the intermediate map-outputs.
- The key (or a subset of the key) is used to derive the partition, typically by a **hash function**.
- The total number of partitions is the same as the number of reduce tasks for the job.
- Hence this controls which of the **m** reduce tasks the intermediate key (and hence the record) is sent to for reduction.
- [HashPartitioner](#) is the default Partitioner.

Job Configuration

- [**Job**](#) represents a MapReduce job configuration.
 - Job is the primary interface for a user to describe a MapReduce job to the Hadoop framework for execution.
- Job is typically used to specify the **Mapper**, **combiner** (if any), **Partitioner**, **Reducer**, **InputFormat**, **OutputFormat** implementations.
- Optionally, Job is used to specify other advanced facets of the job such as
 - the **Comparator** to be used,
 - files to be put in the **DistributedCache**,
 - whether intermediate and/or job outputs are to be **compressed** (and how),
 - whether job tasks can be executed in a *speculative* manner ([setMapSpeculativeExecution\(boolean\)](#)) / ([setReduceSpeculativeExecution\(boolean\)](#)),
 - maximum number of attempts per task ([setMaxMapAttempts\(int\)](#)) / ([setMaxReduceAttempts\(int\)](#)) etc.
- Of course, users can use [**Configuration.set\(String, String\)**](#) / [**Configuration.get\(String\)**](#) to set/get arbitrary parameters needed by applications.

- The **MRAppMaster** executes the Mapper/Reducer *task* as a child process in a separate jvm.
 - The child-task inherits the environment of the parent **MRAppMaster**.
 - The user can specify additional options to the **child-jvm** via the **mapreduce.{map|reduce}.java.opts** and configuration parameter in the Job
 - such as non-standard paths for the run-time linker to search shared libraries via -Djava.library.path=<> etc.
 - If the **mapreduce.{map|reduce}.java.opts** parameters contains the symbol **@taskid@** it is interpolated with value of **taskid** of the MapReduce task.

Task Execution & Environment

- Here is an example
 - showing jvm GC logging,
 - and start of a passwordless JVM JMX agent so that it can connect with jconsole and watch child memory, threads and get thread dumps.
 - It also sets the maximum heap-size of the map and reduce child jvm to 512MB & 1024MB respectively.
 - It also adds an additional path to the java.library.path of the child-jvm.

```

Map Parameters

- A record emitted from a map will be serialized into a **buffer** and metadata will be stored into accounting buffers.
 - When either the serialization buffer or the metadata exceed a threshold, the contents of the buffers will be sorted and written to **disk** in the background while the map continues to output records.
 - If either buffer fills completely while the spill is in progress, the map thread will **block**.
 - When the map is finished, any remaining records are written to disk and all on-disk segments are merged into **a single file**.
 - Minimizing the number of spills to disk can decrease map time, but a larger buffer also decreases the memory available to the mapper.

Name	Type	Description
mapreduce.task.io.sort.mb	int	The cumulative size of the serialization and accounting buffers storing records emitted from the map, in megabytes.
mapreduce.map.sort.spill.percentage	float	The soft limit in the serialization buffer. Once reached, a thread will begin to spill the contents to disk in the background.

- Each reduce
 - fetches the output assigned to it by the **Partitioner** via **HTTP** into **memory** and periodically merges these outputs to **disk**.
 - If **intermediate compression** of map outputs is turned on, each output is decompressed into memory.
 - The following options affect the **frequency** of these merges to disk prior to the reduce and the **memory** allocated to map output during the reduce.

Shuffle/Reduce Parameters

Name	Type	Description
mapreduce.task.io.soft.factor	int	Specifies the number of segments on disk to be merged at the same time. It limits the number of open files and compression codecs during merge. If the number of files exceeds this limit, the merge will proceed in several passes. Though this limit also applies to the map, most jobs should be configured so that hitting this limit is unlikely there.
mapreduce.reduce.merge.inmem.thresholds	int	The number of sorted map outputs fetched into memory before being merged to disk. Like the spill thresholds in the preceding note, this is not defining a unit of partition, but a trigger. In practice, this is usually set very high (1000) or disabled (0), since merging in-memory segments is often less expensive than merging from disk (see notes following this table). This threshold influences only the frequency of in-memory merges during the shuffle.
mapreduce.reduce.shuffle.merge.percent	float	The memory threshold for fetched map outputs before an in-memory merge is started, expressed as a percentage of memory allocated to storing map outputs in memory. Since map outputs that can't fit in memory can be stalled, setting this high may decrease parallelism between the fetch and merge. Conversely, values as high as 1.0 have been effective for reduces whose input can fit entirely in memory. This parameter influences only the frequency of in-memory merges during the shuffle.
mapreduce.reduce.shuffle.input.buffer.percent	float	The percentage of memory- relative to the maximum heapsize as typically specified in mapreduce.reduce.java.opts- that can be allocated to storing map outputs during the shuffle. Though some memory should be set aside for the framework, in general it is advantageous to set this high enough to store large and numerous map outputs.
mapreduce.reduce.input.buffer.percent	float	The percentage of memory relative to the maximum heapsize in which map outputs may be retained during the reduce. When the reduce begins, map outputs will be merged to disk until those that remain are under the resource limit this defines. By default, all map outputs are merged to disk before the reduce begins to maximize the memory available to the reduce. For less memory-intensive reduces, this should be increased to avoid trips to disk.

Configured Parameters

- The following properties are localized in the job configuration for each task's execution:

Name	Type	Description
mapreduce.job.id	String	The job id
mapreduce.job.jar	String	job.jar location in job directory
mapreduce.job.local.dir	String	The job specific shared scratch space
mapreduce.task.id	String	The task id
mapreduce.task.attempt.id	String	The task attempt id
mapreduce.task.is.map	boolean	Is this a map task
mapreduce.task.partition	int	The id of the task within the job
mapreduce.map.input.file	String	The filename that the map is reading from
mapreduce.map.input.start	long	The offset of the start of the map input split
mapreduce.map.input.length	long	The number of bytes in the map input split
mapreduce.task.output.dir	String	The task's temporary output directory

Job Submission & Monitoring

- The job submission process involves:
 - Checking the input and output specifications of the job.
 - Computing the **InputSplit** values for the job.
 - Setting up the requisite accounting information for the **DistributedCache** of the job, if necessary.
 - Copying the **job's jar** and **configuration** to the MapReduce system directory on the **FileSystem**.
 - Submitting the job to the **ResourceManager** and optionally monitoring it's status.
- Job history files are also logged to
 - user specified directory **mapreduce.jobhistory.intermediate-done-dir** and **mapreduce.jobhistory.done-dir**, which defaults to job output directory.
- User can view the history logs summary in specified directory using the following command **\$ mapred job -history output.jhist**
 - This command will print job details, failed and killed tip details.
 - More details about the job such as successful tasks and task attempts made for each task can be viewed using the following command **\$ mapred job -history all output.jhist**

- Users may need to **chain** MapReduce jobs to accomplish complex tasks which cannot be done via a single MapReduce job.
 - This is fairly easy since the output of the job typically goes to **distributed file-system**, and the output, in turn, can be used as the input for the next job.
- However, this also means that the onus on ensuring jobs are complete (success/failure) lies squarely on the clients.
- In such cases, the various job-control options are:
 - [Job.submit\(\)](#) : Submit the job to the cluster and return immediately.
 - [Job.waitForCompletion\(boolean\)](#) : Submit the job to the cluster and wait for it to finish.

- InputFormat describes the input-specification for a MapReduce job.
- The MapReduce framework relies on the InputFormat of the job to:
 - Validate the input-specification of the job.
 - Split-up the input file(s) into logical **InputSplit** instances, each of which is then assigned to an individual Mapper.
 - Provide the **RecordReader** implementation used to glean input records from the logical **InputSplit** for processing by the Mapper.
- The default behavior of file-based **InputFormat** implementations,
 - is to split the input into *logical* InputSplit instances based on the **total size, in bytes, of the input files**.
 - However, the **FileSystem blocksize** of the input files is treated as an upper bound for input splits.
 - A lower bound on the split size can be set via **mapreduce.input.fileinputformat.split.minsize**.
- TextInputFormat is the default InputFormat.

- InputSplit represents the data to be processed by an individual Mapper.
 - Typically **InputSplit** presents a byte-oriented view of the input, and it is the responsibility of **RecordReader** to process and present a record-oriented view.
- FileSplit is the default **InputSplit**.
 - It sets `mapreduce.map.input.file` to the path of the input file for the logical split.

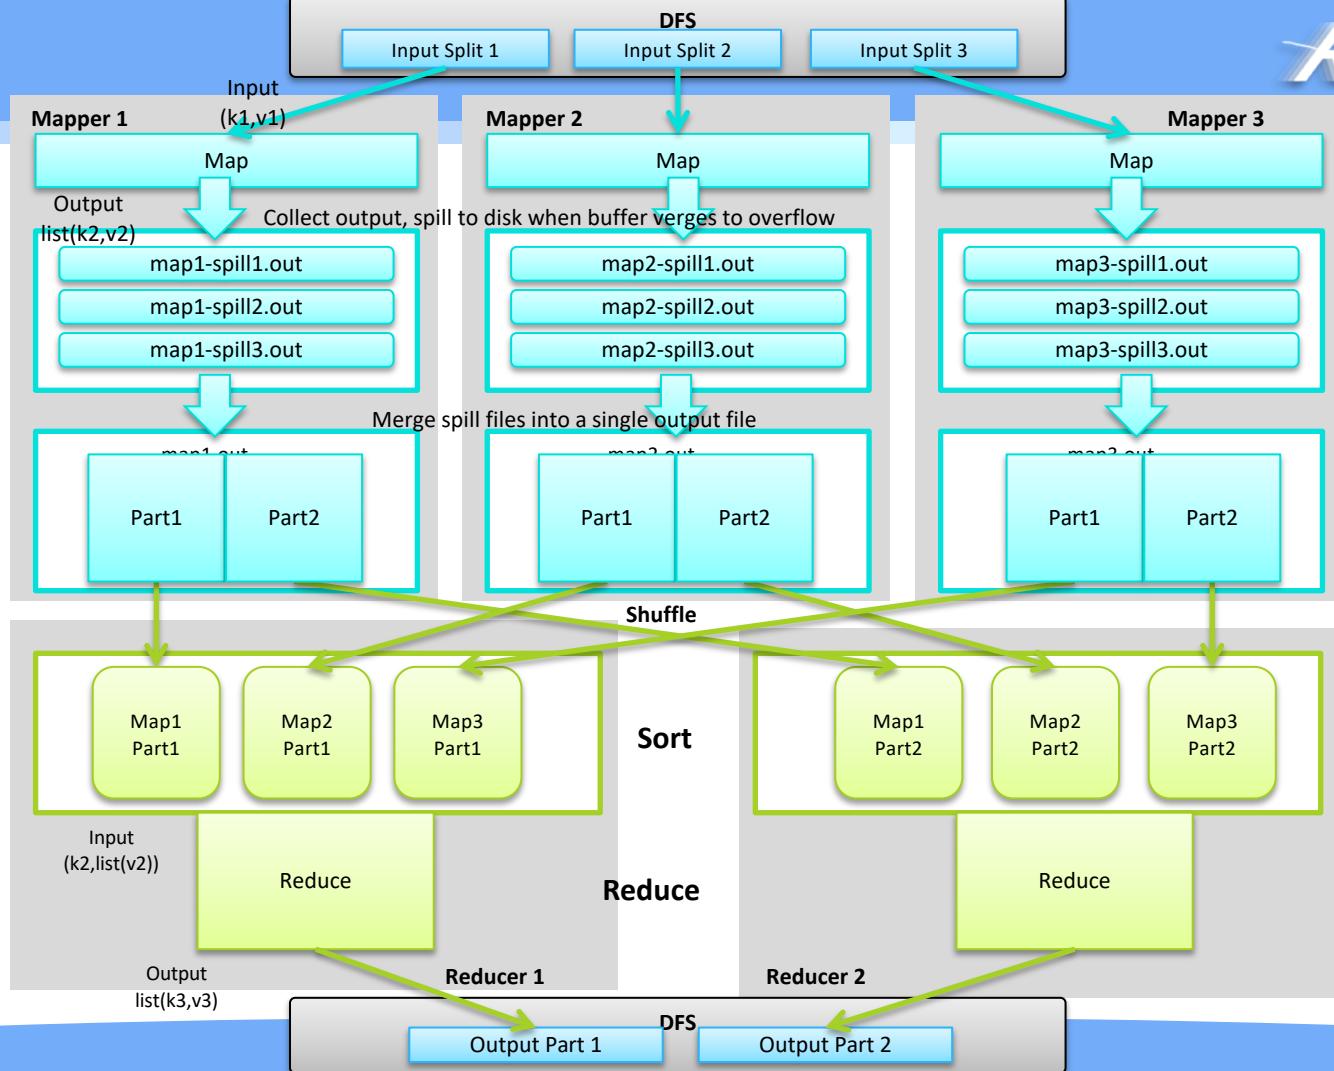

- RecordReader reads **<key, value>** pairs from an **InputSplit**.
 - Typically the **RecordReader** converts the byte-oriented view of the input, provided by the **InputSplit**, and presents a record-oriented to the Mapper implementations for processing.
 - **RecordReader** thus assumes the responsibility of processing record boundaries and presents the tasks with keys and values.

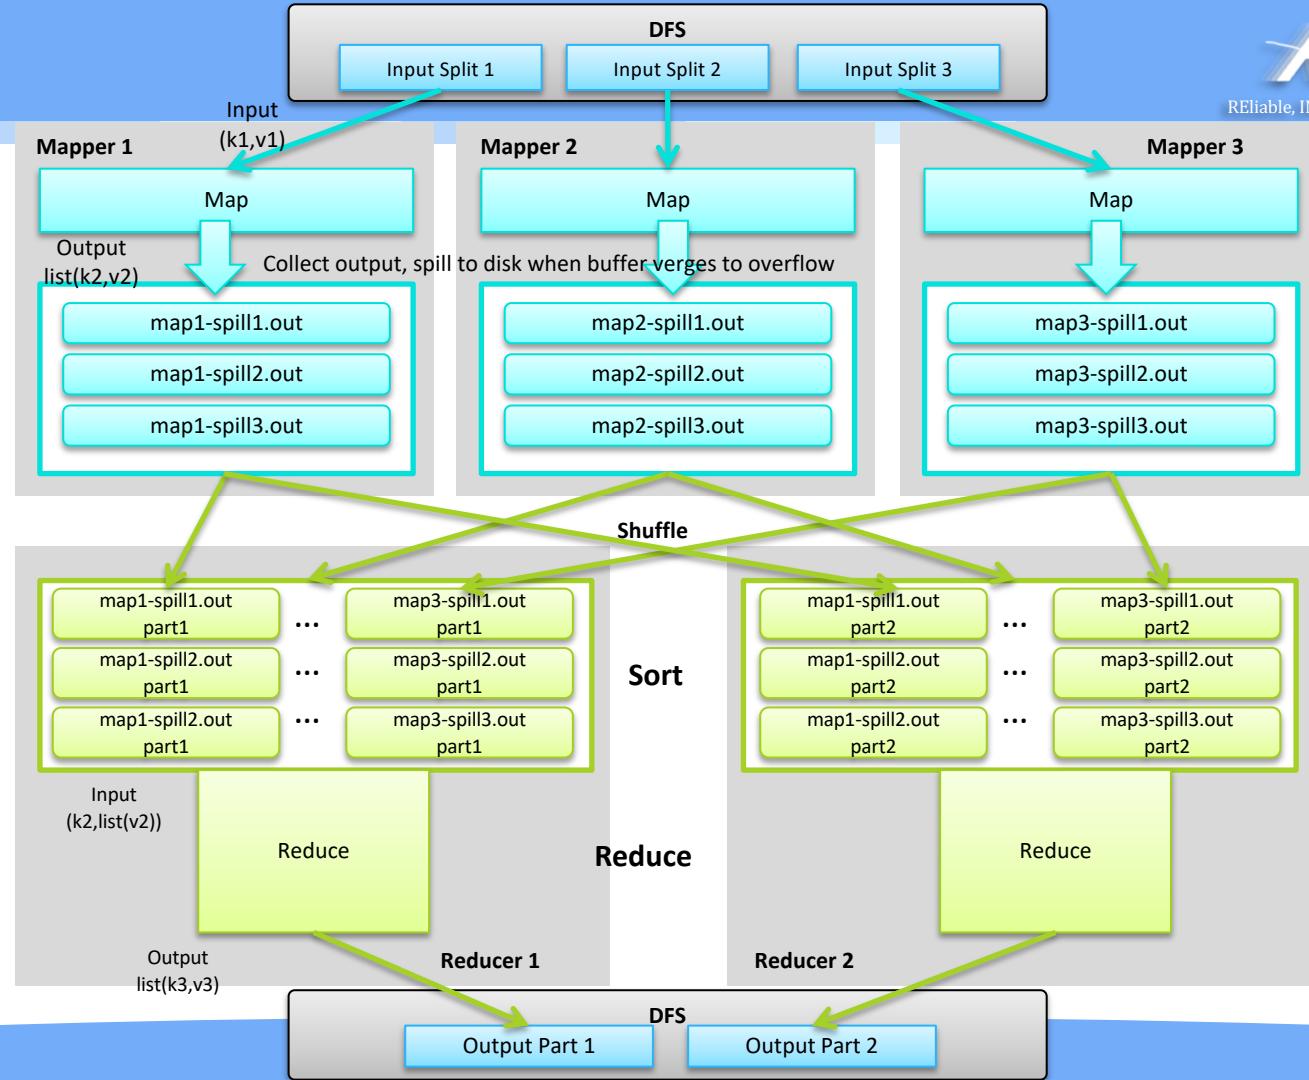

- **OutputFormat** describes the output-specification for a MapReduce job.
- The MapReduce framework relies on the **OutputFormat** of the job to:
 - **Validate** the output-specification of the job; for example, check that the output directory doesn't already exist.
 - Provide the **RecordWriter** implementation used to write the output files of the job. Output files are stored in a **FileSystem**.
- **TextOutputFormat** is the default OutputFormat.

- [OutputCommitter](#) describes the commit of task output for a MapReduce job.
- The MapReduce framework relies on the **OutputCommitter** of the job to:
 - Setup the job during initialization.
 - Cleanup the job after the job completion.
 - Setup the task temporary output.
 - Task setup is done as part of the same task, during task initialization.
 - Check whether a task needs a commit.
 - This is to avoid the commit procedure if a task does not need commit.
 - Commit of the task output.
 - Once task is done, the task will commit it's output if required.
 - Discard the task commit.
 - If the task has been failed/killed, the output will be cleaned-up.
 - If task could not cleanup (in exception block), a separate task will be launched with same attempt-id to do the cleanup.
- **FileOutputCommitter** is the default OutputCommitter.

- [RecordWriter](#) writes the output <key, value> pairs to an output file.
- **RecordWriter** implementations write the job outputs to the [**FileSystem**](#).

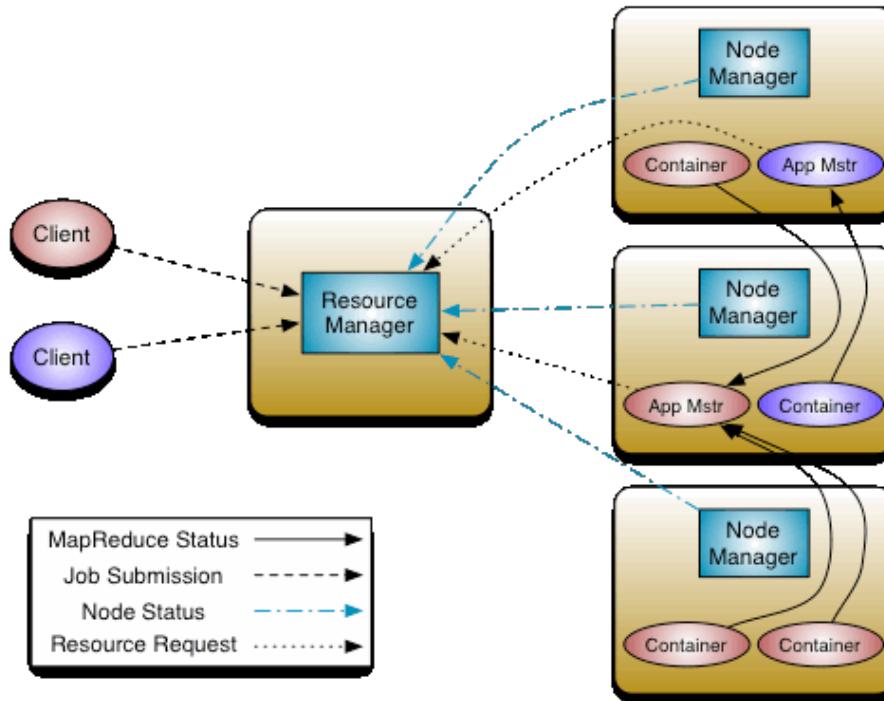

- **Submitting Jobs to Queues**
- **Counters**
- **DistributedCache**
- **Profiling**
- **Debugging**
- **Data Compression**
- **Skipping Bad Records**

- **Apache Hadoop NextGen MapReduce (YARN)**

- MapReduce has undergone a complete overhaul in hadoop-0.23 and we now have, what we call, MapReduce 2.0 (MRv2) or YARN.
- The fundamental idea of MRv2 is to split up the two major functionalities of the JobTracker, **resource management** and **job scheduling/monitoring**, into separate daemons.
- The idea is to have a global **ResourceManager (RM)** and per-application **ApplicationMaster (AM)**.
- An application is either a single job or a DAG of jobs.

- The **ResourceManager** has two main components: **Scheduler** and **ApplicationsManager**.
 - The Scheduler is responsible for allocating resources to the various running applications subject to familiar constraints of capacities, queues etc.
 - The Scheduler performs its scheduling function based the resource requirements of the applications;
 - it does so based on the abstract notion of a resource *Container* which incorporates elements such as memory, cpu, disk, network etc. In the first version, only memory is supported.
 - The Scheduler has a pluggable policy plug-in, which is responsible for partitioning the cluster resources among the various queues, applications etc.
 - The current Map-Reduce schedulers such as the **CapacityScheduler** and the **FairScheduler** would be some examples of the plug-in.

- The ApplicationsManager is responsible for
 - accepting job-submissions,
 - negotiating the first container for executing the application specific ApplicationMaster
 - and provides the service for restarting the ApplicationMaster container on failure.
- The NodeManager is the per-machine framework agent
 - who is responsible for containers,
 - monitoring their resource usage (cpu, memory, disk, network)
 - and reporting the same to the ResourceManager/Scheduler.
- The per-application ApplicationMaster has the responsibility of
 - negotiating appropriate resource containers from the Scheduler, tracking their status and monitoring for progress.

- 在Hadoop的MapReduce Tutorial中(<https://hadoop.apache.org/docs/stable/hadoop-mapreduce-client/hadoop-mapreduce-client-core/MapReduceTutorial.html>)，给出了一个WordCount 2.0版本的实现，相比1.0版本，它增加了对若干Hadoop MR特性的运用。请你参考这个2.0版本的实现，在你的E-BookStore中增加如下的功能，**为方便起见，你可以将该功能开发成单独的工程**：
 1. 将你的系统中所有图书的简介按照图书类型分别存储到多个文本文件中，例如，所有计算机类图书的简介存储在CS.txt中，科幻小说的简介存储在Fiction.txt中。请你构建多个这样的文件，作为MR作业的对象。
 2. 编写一个关键词列表，包含若干单词，例如，["Java","JavaScript","C++","Programming","Star","Robot"]等。
 3. 编写一个MR作业，统计所有图书简介中上述每个关键词出现的次数。
- 提交物：
 - 请提交你构造的图书简介文件和关键词列表，以及你编写的类文件。
 - 编写一个Word文档，说明你的程序的运行方式，以及你做了哪些特殊的参数设置，然后截图展示你的运行结果。
 - 在上述Word文档中，说明在你的程序运行时，Mapper和Reducer各有多少个？以及为什么有这样的数量。
- 评分标准：
 1. 能够正确配置并运行 MR 作业，得到正确的结果：3 分
 2. 文档中对相关参数的设置说明合理：1分
 3. 文档中对程序Mapper和Reducer的数量观察正确且解释正确：1 分
 4. 注：第2-3项得分在验收时会让同学们运行程序，以验证你的文档说明是否正确
